

Figure 6 — Activation dilution tradeoff (FAS)

noise sweep: $\rho = -0.44$

distractor sweep: $\rho = -0.66$

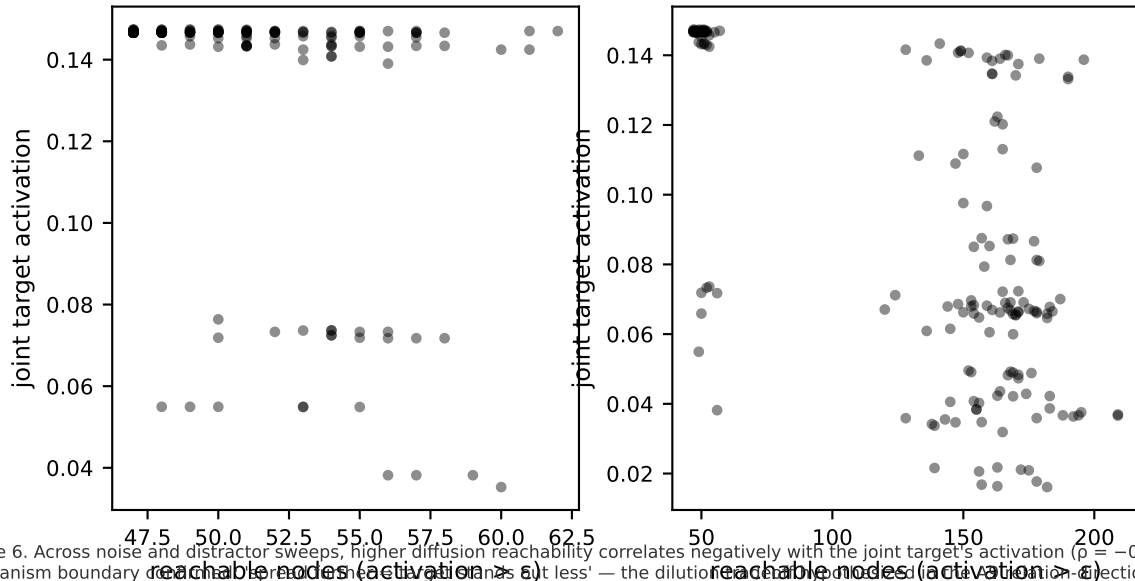

Figure 6. Across noise and distractor sweeps, higher diffusion reachability correlates negatively with the joint target's activation ($\rho = -0.44 / -0.66$). Mechanism boundary detection is performed on the 'large dilution' — the dilution tradeoff is not observed in the 'small dilution' condition.
